### 1. Introduction.

This paper reports the results of the study about the analysis of the changes occurred in the fields of Tokachi district, where we regarded as the test site of this study, using photographic treatment and the density slicing instruments.

This study was performed by following members:

Michikazu Fukuhara of Upland Farming Division, Hokkaido National Agricultural Experiment Station, Yoshizumi Yasuda and Yasubumi Emori of Institute of Color Technology, Faculty of Engineering, Chiba University.

### 2. Techniques.

B & W bulk positives of 4, 5, 7 bands in the two scenes of LANDSAT data, the one obtained on 11 June 1975, the other, 24 May 1973, were prepared.

After they were enlarged to 1:200,000 scale, the ratio images of 1975/1973 of each band were made.

These images were analysed using slicing instrument (GRAF-COLOR 905), and the color-coded density maps obtained were interpreted.

### 3. Accomplishment.

1975/1973 ratio images are shown in photo-1 (band 4), photo-2 (band 5) and photo-3 (band 7). In these prints, the red colored portion indicates the increased reflectance, blue-colored, the decreased.

Pattern, expressed in the prints of the color-coded maps are considered to be classified as follows:

1). The place where land management changed. For instance, the places where were allowed fallow in 1973 and became planted in 1975 (photo-3 <sup>red</sup> blue parts).

2). Seasonal variation of vegetation. In natural or grazed grasslands, the ground surface is covered with dead grass in May, but in June, it is covered with vigorously grown grass (photo-1 blue, photo-2 blue).

3). Apparent change caused by difference of relative reflectance among objects in images. River beds or street area where no vegetation is seen (photo-1 red). Alluvial soils or volcanic ash soils mixed with subsoils (photo-2 red).

4). The part difficult to interpret (photo-3 blue).

#### 4. Conclusion.

Multidate analysis of LANDSAT data was tested using ratio image method. As by this method, many informations have been obtained which cannot be obtained by means of single scene analysis, this method is expected to have <sup>many</sup> ~~great~~ possibility to interpret the imageries of agricultural fields which show large annual fluctuation.

@abs The author has identified the following significant results.

Using MSS channels 5 and 7 and a supervised classification system with a PPD classification algorithm, it was possible to map the exact areal extent of the snow cover and of the transition zone with melting ~~snow~~ snow

patches and snow free parts of various sizes over a large area under different aspects such as relief, exposure, <sup>and</sup> shadows, etc. A correlation of the data from ground control, areal underflights and earth-resources satellites provided a very accurate interpretation of the melting procedure of snow in high mountains.
